

Randish - Echo

I. Intro

Echo - Like an echo, you need to reflect the amazing features your project has in your writing. Echo is a full stack website that links to GitHub through GitHub api(s). It employs a Large Language Model (LLM) to reach the lines in the project and dump the info into a text file locally to use later. It is much stronger than using an LLM directly as this has a pre-configured and pre backend that acts as an api instead of a full stack website. This api exists as a separate repository and is added onto echo as a submodule.

II. Understanding scope

The LLM will do its best to separate the files into separate chunks of manageable sizes and understand the scope of these files and dump the info into a temporary text file.

It then takes this temporary text file and starts to wrap on and create usable version of different type of documentation - later mentioned

III. Types of Documentation

- Internal
- External
